Nonbranch Lean import preflight

Source and receipt reconciliation · 2026-11-11

This report is a source-only preflight. It records the tracked import closure and existing receipts. It adds no compiler invocation, theorem verdict, experiment attempt, or scientific promotion.

Pinned source and closure

The source tree is pinned to crypto commit `4f8d8bf375348180cf1518ecf9d913a2ddca7ad2`. The five archived pencil roots and their dependencies are unchanged at gate commit `cce79de90322deb6e598c28a63b0f3cb75e2fb02`.

The static basename resolver finds **41 tracked Lean sources** and **53 internal import edges** from the five roots. Three edges cross into the projective-law formal directory, which contributes 36 sources. It finds no missing or ambiguous tracked import. This is a source-name map, not Lean elaboration.

The 36 projective-law sources have nearest toolchain pin Lean 4.34.1. The archived pencil roots have no nearest pin; retained native commands explicitly used Lean 4.34.1. The projective-law Lake manifest has SHA-256 `ebc6643e694eaa4a60ab2b727c96253f3d88694e7ecb404f2176a548eedbe98d` and Mathlib revision `d13f23b723b8a846827a245b89c10fc7d3f11612`.

Recorded attempt states

Record	Observed status
Original native compiler	`Nonbranch` exit 0; `IndependentControls` exit 1. Compiler receipt says failed, machine review incomplete, scientific execution false.
Dependency custody	Separate pre and post receipts each checked 16,736 files and 3,111,892,318 bytes.
Later correction	Candidate SHA-256 `448d5ab601e955b93a9071d6b5f932b38850f5728c9cf2c3fc3eb5b3742bb35d`; proposed_uncompiled, zero invocations; original ceiling 3 of 3; no new attempt authorized.
Hosted proof gate	Run 42773450127 reported FAIL_build for five standalone roots without cross-directory imports. This identifies a gate workspace gap.

Reproduction and next proof boundary

The accompanying `imports.json` records root paths, source SHA-256 values, toolchain pins, and internal edges. Recompute a listed hash from the pinned tree with `git show <commit>:<path> | sha256sum`. The SVG renders the directory-level closure and recorded states.

A prospective proof attempt requires a separately authorized envelope, an immutable source and dependency workspace at the recorded pins, independent source-fidelity review, explicit named-module compilation, transitive axiom readback, and negative controls. The correction remains unverified until those checks exist.

Source: repository receipts and pinned tracked sources. No historical source, receipt, deadline, or retry count changed.
