Independent C-zero interpolation review

No blocking discrepancy found at the normalized field interpolation scope. Nine main declarations, six producer controls, six reviewer declarations (including two input witnesses), and 21 separate axiom readbacks pass in the isolated review root. Readbacks contain only propext, Classical.choice and Quot.sound. Final checks have unchanged input bindings, and three copied producer modules match the stable producer hashes. The producer was not modified.

The prospective plan and blind derivation were written before inspecting producer CZero.lean. The independently derived B Bezout identity, A/B coefficient relations, and MINUS-sign common interpolant match the producer statements. Explicit Bezout implies IsCoprime when B is nonzero. Each input residual divisibility transports to the common interpolant; coprimality then yields product divisibility. The theorem correctly assumes both input divisibilities and does not insert the final product divisibility as a premise.

Exact source mapping: retained projective_law_gate.rs950-1023 has B=dq*(q2*r1-q1*r2)-dr^2, A=dq*(dt*q2-ds*r2)-dr*dt, C=dq*dt-dr*ds. Setting normalized support polynomials u_i=X^2+q_i*X+r_i and ordinate polynomials v_i=s_i*X+t_i, lambda=A/B and C=0 yield l=v1-lambda*u1=v2-lambda*u2. The source unit-scale output ordinate is -l(x), with x=q1+q2+lambda^2. The coefficient identities require no characteristic restriction beyond Field; smoothness, monic quintic shape and curve degree are not needed for this component.

Reviewer controls include an actual full theorem application: rational inputs u1=X^2+X+2, u2=X^2+1, v1=4X+5, v2=X+2 give lambda=3. Define l=v1-3u1 and f=l^2+u1*u2; explicit witnesses prove both required input divisibilities, then product_divides_residual is applied. This constructed f is an algebraic fixture, not a smooth genus-two curve assertion. Additional controls cover equal q with distinct constant coefficients, the failure of a PLUS-sign interpolant, and normalized output ordinate orientation. The first reviewer attempt failed from constant-polynomial coercion and ambiguous support notation; reviewer2 fixes these explicitly, preserving the failed receipt.

Weighted boundary: native qic,ric,sic,tic are crossed coordinates with different weights. The normalized theorem does not identify A/B directly with a weighted slope without scale transport. Native output curve membership, class-sum equality, word overflow/canonicality and compiled Rust equivalence remain separate obligations. This review establishes neither those claims nor a new performance result. No scientific execution occurred.

Independence disclosure: reviewer previously authored residual construction and signed-graph algebra components; the CZero interpolation producer was another agent. Review of these new numerator, Bezout and interpolation statements used a blind derivation plus isolated replay. Imported dependency cache remains the recorded trust boundary.
