Nonmonic division: checked native word path

Leading-word inverse and coefficient shortcuts
Native modpow proof + prime/canonical assumptions → c = lead(R) / lead(B)

Word subtraction traversal and trimming
Top coefficient cancels → remainder length strictly decreases

Indexed quotient overwrite + recursive invariant
Fresh slot assignment preserves Q·B + R and terminates within input length

Canonical word quotient endpoint
A = wanted·B → returned quotient decodes to wanted; remainder is empty

19 main declarations · 22 fixed controls · 41 named readbacks

Explicit boundaries: native allocation/dispatch refinement and pegcd composition

Formal source model; no scientific measurements or new campaign execution
