Private runtime source integration

The separate private assembly and qualification sources now have matching interfaces and an independent non-author source review. All 20 supervisor and 14 qualifier software controls passed. The reviewer participated in advisory design but authored neither implementation.

Corrections checked. Exact context and token modes despite umask 0077; narrowly permitted predecessor-disk access; complete four-file callback snapshot; actual phase expiry; daemon readiness; managed child discovery; retained terminal unit state and explicit stop reconciliation. The original qualifier packet remains preserved alongside its corrected version.

Gate check. GCC 11.5.0 accepted the exact C source with -Wall -Wextra -Werror -fsyntax-only. No executable was produced by this check. Source requires a complete exact nonce and host-side container cgroup checks before payload release.

Evidence boundary. These are mock/static and temporary-file tests, not actual systemd, mount, Docker or native PID1-gate observations. Both phase drafts remain unadmitted. Native gate controls, concrete runtime admission and actual resource/cleanup readback remain required. Unknown surviving processes or mounts prohibit automatic retry.

Review artifacts. independent-review.json binds eight exact sources and records all 34 checks and limitations. PLAN.md, syntax-check-plan.json and raw syntax exit/output records preserve this integration check. Full matched-cohort and mathematical obligations remain unchanged.
