Independent source review

branch-helper-replay-20261109

Source-only; no compiler, payload or measurement executed.

1. The exact freeze and every frozen packet file matched; all 26 retained source/artifact entries matched current bytes and sizes. Thirteen prerequisite modules are retained, and the failed helper is absent from that list.

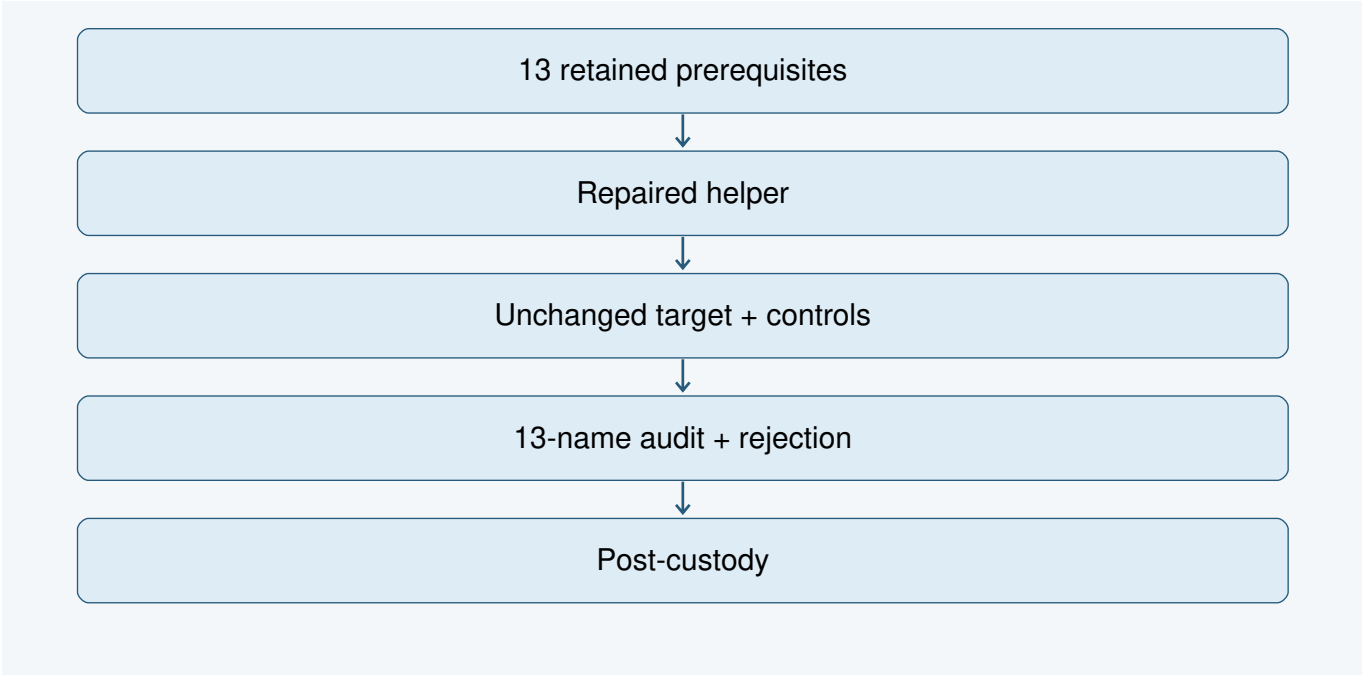
2. The repaired helper e824907a is the already reviewed four-proof-step correction. Target, rational controls, thirteen-name readback and expected-failure source remain unchanged. The five calls stop on an unexpected exit before any later target call.

3. retained_check creates a private cache exclusively, rejects symlinks and extra members, verifies original and copied hashes, rejects retained/new module collisions, and repeats checks before and after compilation and during post-custody. Import order is fresh workspace, retained cache, frozen baseline.

4. The launcher preserves exact systemd invocation cleanup, one-attempt admission and post-custody after compiler failure. Limits are 900/600/900 seconds (2400 total), one CPU, 8 GiB, zero swap, with the unchanged absolute deadline. Shared baseline custody retains the explicit transient-concurrent-change caveat.

5. Publication/review/ledger/lease receipt hashes and explicit release are checked. Current null ledger fields and false release template prevent this source packet from admitting itself. No new runtime qualification or compiler result is asserted.

Argument and custody map



Remaining step: Coordinator supplies current ledger and exact published final release; then the five-call bounded attempt can be considered.

Inputs and precise hashes: review.json and snapshot/.

KB unavailable: no loaded search/status tools; scripts/research-kb absent. Used exact retained source/review bindings and pinned Mathlib declarations.

Source review is not kernel acceptance or execution admission; compiled dependencies retain existing Lean trust boundary.
