Five ECDLP follow-ups: verified operation evidence

Evidence date: 2026-10-20. **Pricing:** M+0.5S+10I; 0.1M per declared native logical operation except the cubic arithmetic gate, which has no native charge. All ratios below are operation counts, not qualified wall speed.

Two complete genus-2 cohorts

The two-choice collector and the projective numerator chart each ran on all 1,260 original exact-order source targets (21 curves, 60 targets each, 16–40 bits). For the projective chart, all 3,780 arm records were source-verified and independently replayed. At the stated price, projective/affine is **0.642714×** and projective/source-rho is **2.881445×** pooled. The full 12×3 price grid and per-curve rows are in `results/genus2-projective-price-grid.csv`.

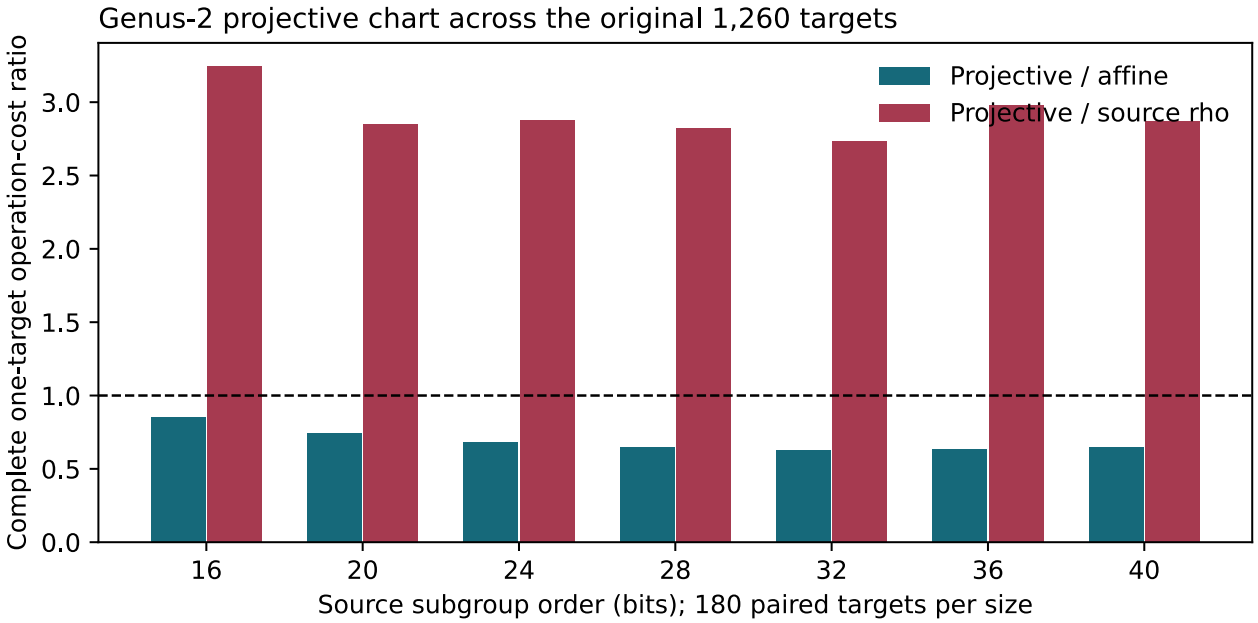

Figure 1: Complete paired operation-cost ratios by order size; 180 targets at each size.

Mixed fibers: pair table and polynomial all-roots solvers

All 540 pair-table candidate records on nine eligible prime-order curves were source-verified; native reanalysis retained every price and curve. Homogeneous, mixed and matched-random pooled ratios to rho are 3.6435×, 3.2222× and 3.7180×.

The Semaev-S4 exhaustive-polynomial solver also recovered all 540 scalars on the same 180 targets and checked every answer on the source. Homogeneous, mixed and matched-random pooled costs are 57.8840×, 32.2975× and 34.4846× rho. All 36 pooled price cells lose to rho and the corresponding pair-table arm.

The native F4 solver additionally returned exact rational root sets on 2,290 nonidentity DLP queries; 26 identity right-hand sides needed no polynomial system. Its replay recovered and source-verified all 540 scalars. Counting F4 row-reduction multiplications and collector costs gives homogeneous/mixed/random **160899×/232110×/239616×** rho as lower bounds; all 36 pooled cells lose. Symbolic and substitution operations are uncounted, and external msolve remains unavailable.

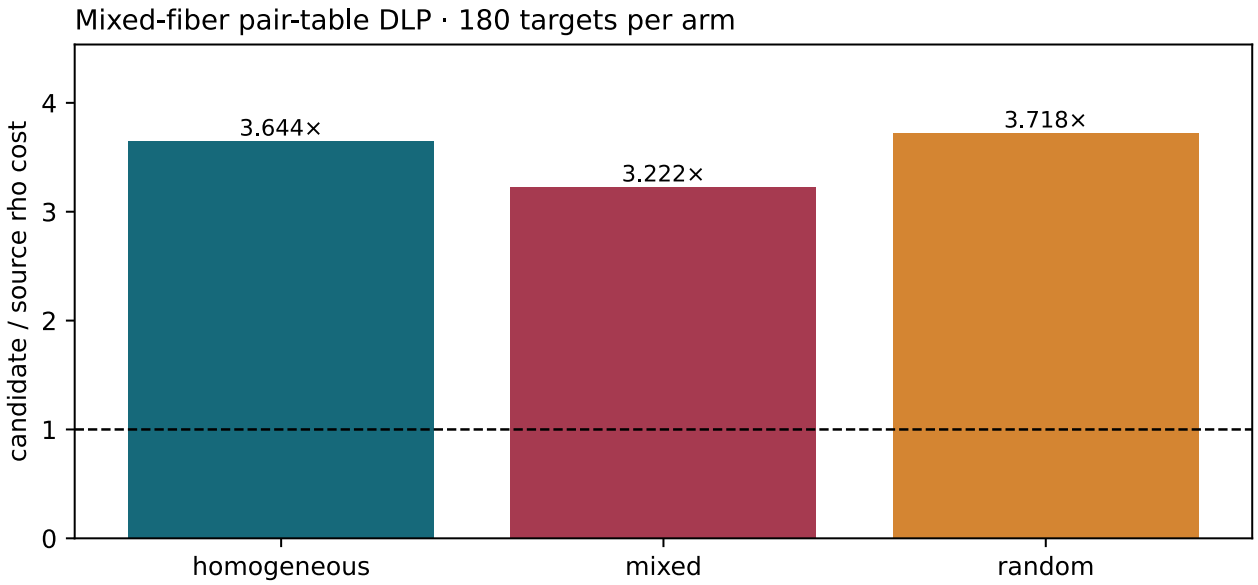

Figure 2: Complete DLP cost ratios; 180 exact-order targets per arm.

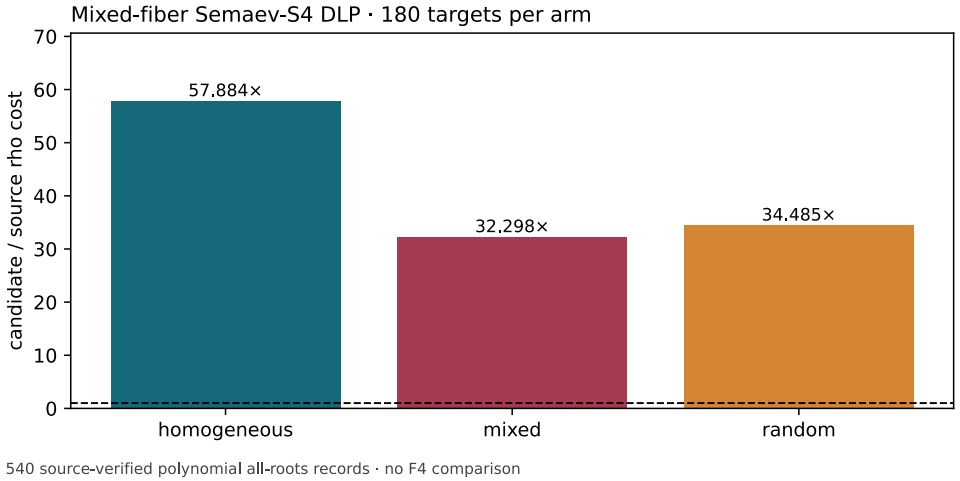

Figure 3: Complete exhaustive Semaev-S4 all-roots DLP costs; 180 exact-order targets per arm.

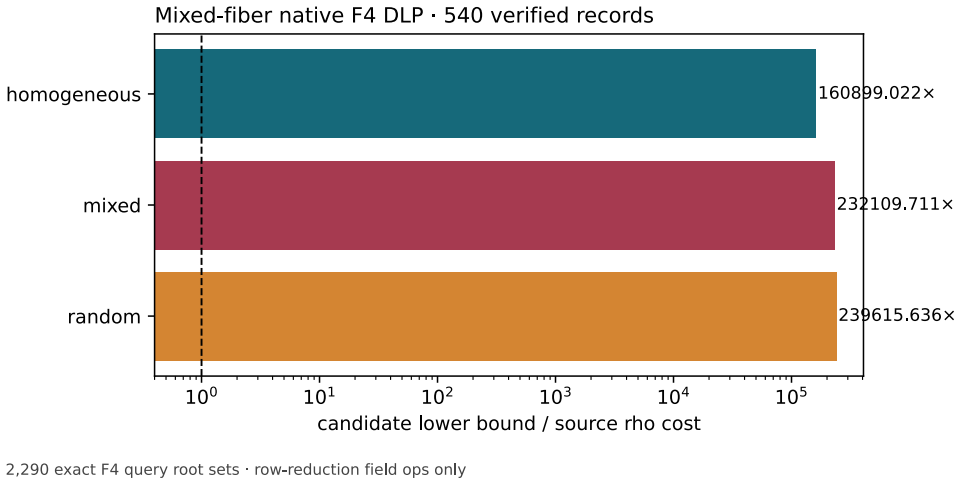

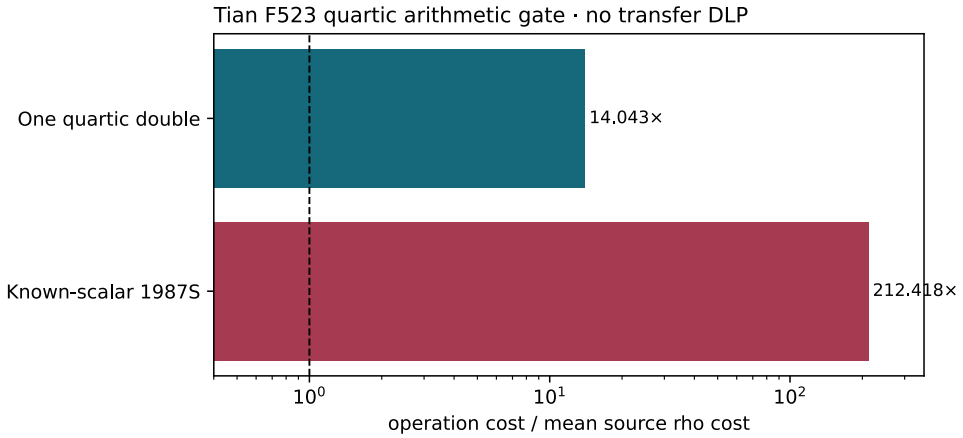

Figure 4: F4-backed DLP lower bounds from counted row-reduction field multiplications; 180 targets per arm.

Cubic transfer and genus-3 odd-kernel escape

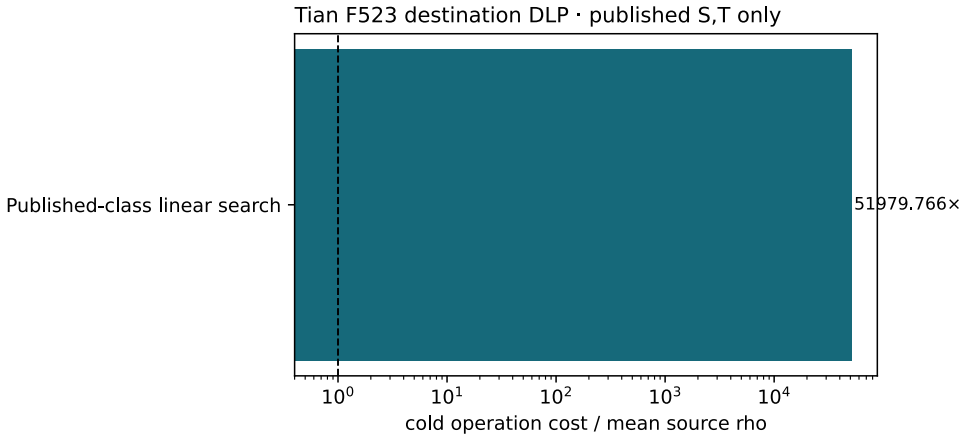

For Tian's published F523 cubic fixture, the 3-kernel and smooth quartic were checked. The six published map functions were evaluated on 100 successive source multiples and Q; all 101 Frobenius-traced divisor classes match the expected Jacobian multiples. The line sieve recovered 1987 from the mapped P and Q classes and checked the answer on source and destination.

Its complete cold cost, including formula evaluation and trace construction, is **645.65×** mean source rho at M+0.5S+10I+0.1A; all 36 price cells lose, spanning 47.14–787.55×. The published-class-only line sieve costs 561.59×. The 20 Smith-negative genus-3 holdouts were materialized, but odd kernels and end-to-end attacks on them remain untested. An independent quotient-from-kernel proof for the cubic fixture remains open.

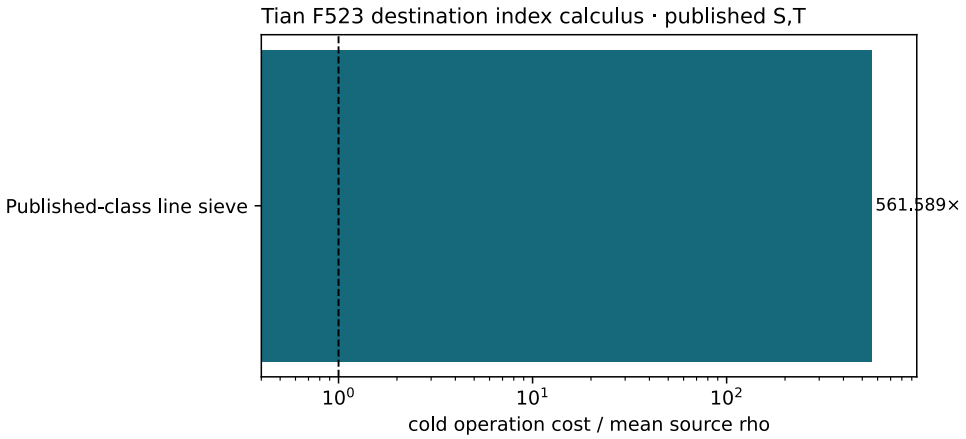

5 independently verified source rho seeds · published destination classes

Figure 5: Arithmetic diagnostic only; one quartic doubling and a known-scalar multiplication divided by the mean of five complete source-rho solves.

one source-verified fixed target · source map and index calculus unexecuted

Figure 6: Cold cost of one verified DLP on published destination classes; no source-to-Jacobian map or index calculus was run.

one source- and destination-verified target · source map unexecuted

Figure 7: Cold cost of published-class line-sieve index calculus, including all relation and descent attempts. Source map absent; operation pricing includes modular additions.

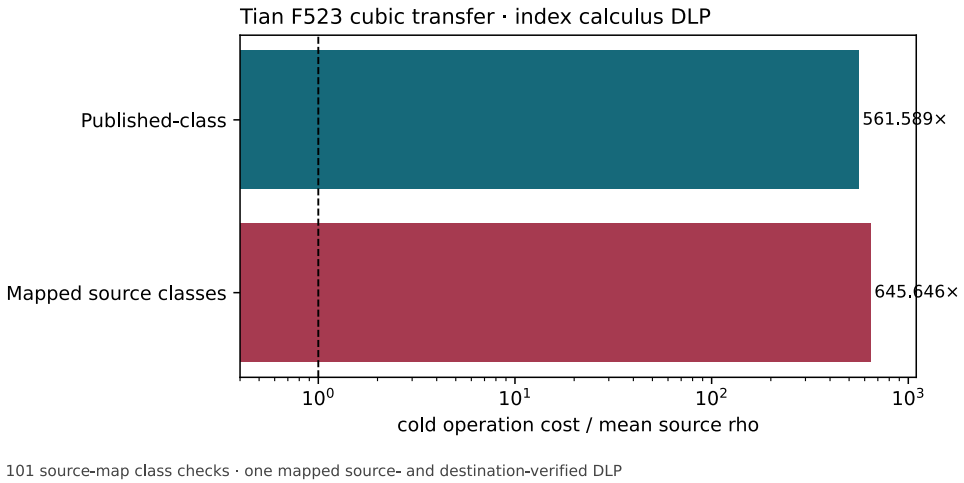

Figure 8: Mapped source-to-answer line-sieve DLP against five optimized source-rho seeds. The published-class-only control omits source mapping.

Evidence: `REPORT.md`, `results/`, `correctness/`, `sessions_projective_chart_v2.tar.zst`, and the seven linked `reports/run-*` PDFs. Negative outcomes and unexecuted routes remain explicit in the report. Literature: Tian's cubic transfer and Tian's genus-3 odd-isogeny construction.
