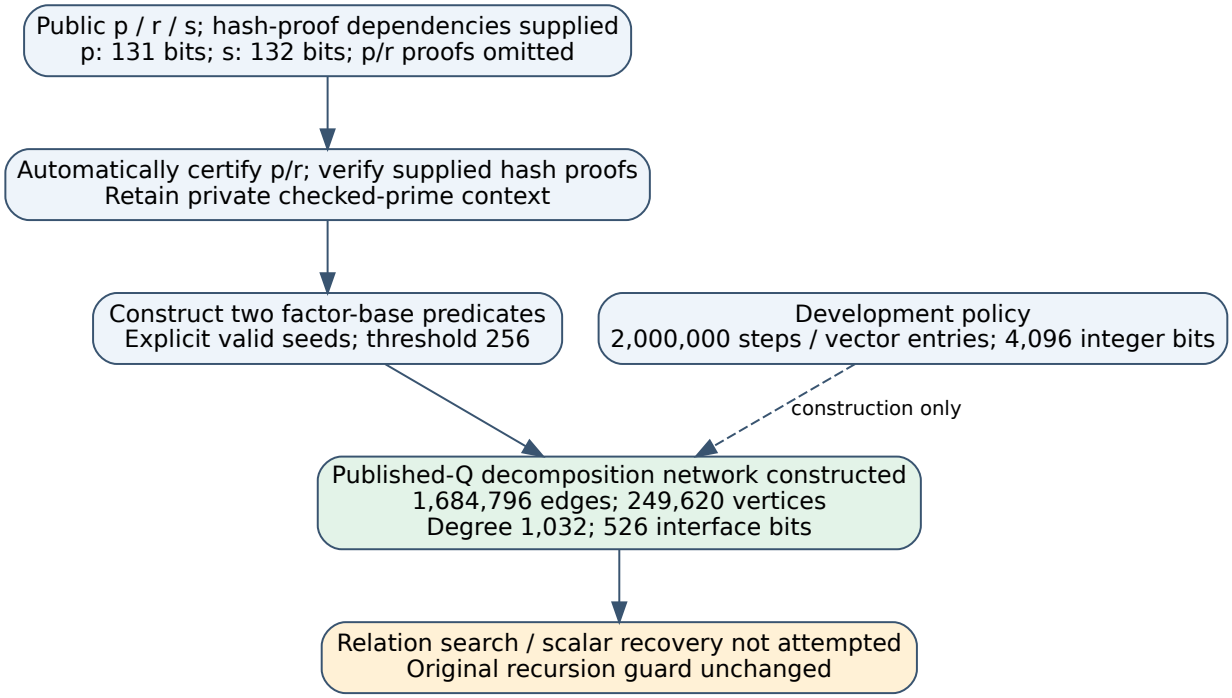
ECCp-131 setup now reaches full network construction

2026-10-30 · exact prime proofs · development validation

The unmodified delivery baseline stops in AKS. The follow-up extends strictly bounded exact primality tests, verifies bundled public proofs automatically, and attempts bounded Pocklington proofs before the exact fallback. The already landed checked-hash context is preserved. No probable prime is accepted as certified.



Observed construction control. The native package passes 94 tests, strict all-target lint, formatting and Rust 1.78 checks. Original-input preflight charges 17,471 abstract steps; explicit certified-hash preflight charges 5,897. The matched construction control deliberately omits p/r certificates: the unchanged baseline exhausts AKS, while the patch charges 19,722 through setup and 19,925 through the network. These are uncalibrated diagnostics; no runtime ratio is asserted. The earlier all-proofs control is retained separately. The graph vector policy is two million; the original fixture’s 200,000-entry cap is too small for this graph. No base enumeration, count, witness or solve was requested by this control.

Validation limit. The broader parent-library run did not finish one unchanged legacy isogeny-walk case before SIGKILL. All 18 missing-fixture failures replay successfully on the same executable after restoration. No full parent-suite pass or general mathematical audit is claimed; the follow-up is held for that remaining validation. Full-parent raw archival also awaits an authenticated S3 connection; its local-only status is explicit.

Sources and replay. Sorenson/Webster, arXiv:1509.00864 Theorem 1.1; HAC Chapter 4 Fact 4.40 and Chapter 3 Algorithm 3.9; pinned Bochum v0.2 Section 3 (fixed prime s in [2p,4p]). README.md, commands.txt, native-setup-check/ and delivery records retain exact source, input, lockfile and output identities.
