Frozen performance-gains dashboard audit

2026-10-21; crypto branch f535212dd762dde6b23a1891eb94c1e9fe28b07a

Scope. Read-only check of the 2026-09-14 summation-polynomial performance page. No benchmark, scientific run, or new measurement was made. The existing chart is on page 2; its source is `docs/performance-gains/summary.svg`.

Source binding. Four source hashes in the page match their committed Git blobs. The two frozen comparisons report 342 ablation runs and 140 confirmation runs, both complete with zero failures. All 804 dashboard rows match their source arrays exactly, and the HTML-embedded data matches the page's JSON file.

Independent arithmetic check. The native Rust checker recomputed 766 individual timing ratios and 32 input-cluster geometric point ratios. All matched. The 32 published intervals are identical to the frozen comparison JSON; the checker did not regenerate the bootstrap distribution. For p=67, seed=11, repetition=0, hash-bound raw outputs give 1,342 reference and 1,199 Horner field multiplications per specialization.

Code check. On the final source, `cargo test -release -lib` passed 4,474 tests with zero failures and 119 ignored. A pre-fix parallel run exposed cross-thread contamination of an opt-in profiling counter; the switch is now local to its requesting thread, with a cross-thread control. Solver arithmetic and archived timing records are unchanged.

Boundary. This historical page distinguishes a local specialization gain from the unproved full-DLP improvement. The graph and all rendered exports remain unchanged because their measured source and conclusion did not change. Interactive JavaScript behavior could not be run here because Node was unavailable. This audit does not validate all historical experiments, prove their implementations in Lean, or establish current public dashboard deployment. The full evidence and commands are in `REPORT.md` beside this PDF.

Existing chart: frozen measurements of 14 September 2026
