Independent target-rank review

Signed duplicate review: fixed algebra controls

Same canonical divisor + both normalized labels → Δa + Δb k = 0

Δb ≠ 0: candidate -Δa/Δb; actual group verification required

Δb = 0: valid labels force Δa = 0; redundant equation

12 fixed controls reproduced. Source insertion remains a proposal.

No blocking discrepancy was found in the stated algebra or proposed source placement. All producer hashes matched. One fixed-checker replay returned exit zero and reproduced the producer result byte for byte.

Rank controls Forest, balanced target-bearing triangle, balanced redundant triangle and unbalanced triangle have left-nullities 0, 1, 1, 0 over F11. The balanced dependence is $(-1, -1, 1)$; its target coefficient distinguishes useful and redundant equations. The graph model still requires a justified field-coordinate interpretation.

Source placement The existing signed-divisor set rejects duplicates before graph insertion at pruned.rs:521. A proposed map can compare the first stored pair with the new sign-normalized pair before rejection. Both labels must receive the sign; first-occurrence graph signs and labels must remain mutually consistent. This is not implemented collector evidence.

Coverage Four duplicate cases, four invalid-assumption fixtures and four rank cases were checked. The fixed F11 checker is not a generic prime-order or group validator. No naturally generated duplicate, Jacobian verification, source trajectory or historical 114-edge forest was rerun. A planted relabeling would test an interface only.

Artifacts REVIEW.md provides derivations and precise limitations. status.json and receipt.json bind the replay; the manifest supplies full artifact hashes. No scientific execution or repository edit occurred.
