Fixed pre-exec gate: prospective control review
Accepted for one bounded native software-check sequence

Pristine gate SHA and every proposal/compiler binding checked before admission.

Separate control translation unit includes actual gate bytes; only main name and mountinfo open are redirected.

Sixteen frozen fixtures cover exact parser, byte-length, nonce and failure cases. Expected assertion count recomputed: 7+9+11+12+6=45.

Original gate main on the ordinary host returns126 before cgroup access/exec; it cannot supply positive container qualification.

Two static builds at120seconds, controls20seconds, total300seconds; child-only environment and fresh private output.

V1 asynchronous signal launch window was identified before execution and retained. V2 records uncertainty before launch and defers signals until ownership is known.

No compile or control execution performed during this review; actual kernel cgroup enforcement remains a later container observation.

Proposal manifest:
