Independent word Add11 review

Weighted Add11 word-model review

Canonical inputs + bounded prime → six canonical decoded outputs

Distinct normalized x → actual modeled cross words differ → distinct guard

Fresh compile / controls / readback: exit 0. Compiler and counters excluded.

No blocking discrepancy was found for the stated literal-word-model correspondence. Producer hashes matched. Fresh module, controls and axiom readback compiled with exit zero; retained dependencies were reused.

Power loop Exponent five follows 5,2,1,0: initial multiplication by one, two conditional squares, final accumulator multiplication. There is no trailing unused square. The exact unroll is reflexive.

Payload Bounded canonical operands permit compositional modular-value decoding. All six payload words are canonical and decode to the reviewed weighted field formula. Expression sharing and operation counts are not established by this value model.

Dispatch Inverse precedes doubling and then the equal-cross assertion. Distinct normalized x with nonzero decoded z excludes equal machine cross words, so the modeled distinct branch is selected.

Boundary Field.n=1, no tables, odd-prime path and normal counter execution are source-mapping conditions. This is not compiled Rust equivalence, normalized word Mumford validity or a group-law/walk proof. No scientific trial or cost claim was produced. REVIEW.md and receipts.json retain details and exact checks.
