Conditional fraction-field pole identity

The pinned Lean file `Common22FractionPole.lean` kernel-checks the fraction-field valuation step conditional on the infinity chart. Let v be a valuation on a field, and assume $w \neq 0$, $w^2 = zu$, $v(u) = 1$, and $z^3 g = G$. The two checked implications are:

Theorem	Additional hypothesis	Conclusion
`unit_chart_pole`	$v(G) = 1$	$v(g) = v(w)^{-6}$
`linear_chart_pole`	$v(G) = v(w)$	$v(g) = v(w)^{-5}$

The proof uses multiplicativity of v, the chart relation, and cancellation of the nonzero value $v(w)$. The first branch corresponds to a unit chart residue; the second to the degree-drop branch. These exponents become pole orders six and five only after w is identified as a normalized local uniformizer of the actual smooth projective curve.

Boundary. The projective infinity stalk, its embedding in the function field, the principal divisor, Mumford reduction, the Pic^0 class equation, and compiled Rust semantics are not supplied by this file. The result changes no target solve or cost ratio. The adjacent CSV records both theorem statuses and a null rho ratio; the SVG graph displays only the conditional exponents.

Replay. Run `lake env lean Common22FractionPole.lean` in the pinned formal directory. The successful axiom output is retained in `fraction-pole-build.log`.
