Retained-duplicate archival design review

The fixed-input scope is internally consistent: one archive hash,60 targets and420 cases, partitioned by full model/G/Q, workload and target identity. Both original labels and first graph signs remain intact. Native label checks and candidate verification are appropriate acceptance conditions; designed fixture provenance is separate from natural trajectories.

Before executable freeze. Bind exact helper/dependency hashes and retained model/order/G/Q/label receipts. Unbound partitions require dispositions, not guessed identities. Root selected complete all420 archival diagnostic dispositions without early answer stop; mark post-terminal rows without production stopping or performance claims. Bound per-target subgroup/model checks and distinguish logical ingests, unique insertions and reference verification accounting.

Natural arm. Freeze an exact list and row bound for eligible already-existing traces or record unavailable. Three-step correctness fixtures do not establish natural trajectory sampling. Missing provenance cannot be repaired by new walks or relabeling in this gate.

The single offline process120-second ceiling, no adaptive extensions, no new samples and all420 dispositions preserve the archival scope. No execution or admission occurred in this review. No performance, natural yield or complete cost ratio is established. Exact proposal hash and pending decisions are in review.json.
