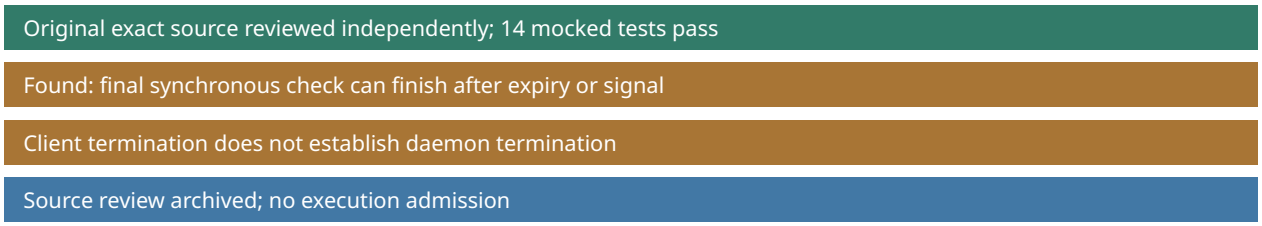
Independent review of original runtime assembler

The original assembler implements exact source/input/reviewer joins, COPY-only build construction, owner/tag attribution, a one-use marker, IID/configuration/layer checks, and unresolved failure handling. Fresh mocked replay passed 14/14 tests. Exact source and supporting file hashes are in review.json. The source matches introduction commit ea7499c8315be99c9bf8b4fe05aadce5b7dbd5a6.



T-1407: source/software checks only; whole-process and daemon containment remain unresolved.

Two admission obligations remain: the final synchronous input check can finish after expiry or a pending signal and still report success; and terminating the client does not prove Docker daemon build termination. Whole-process containment, daemon reconciliation and finite resource/accounting bounds remain external requirements. The one-owner marker is not global duplicate reconciliation, reviewer fields do not authenticate identity, and output polling is not a disk quota. Context checking assumes stable trusted filesystem custody during upload.

The eight recorded local Python child controls were inspected, not replayed or independently checked against their raw archive. They do not cover sudo propagation, root descendants or Docker cancellation. No Docker, sudo, assembly, qualification or scientific payload was invoked during this review. No execution is admitted.

This review was completed independently of original authorship. The reviewer subsequently authored runtime-assembler-v2 to fix final success classification; that new source needs a different independent reviewer. The original packet remains immutable.

Applicable sources: repository AGENTS.md, .agents/skills/report-evidence/SKILL.md, original assembler PLAN.md/REPORT.md and tests, replacement contract/checker, driver control plan/source/report/summary, and the exact proposed Dockerfile. Review is prospective software source fidelity, not experiment evidence or a scientific status transition.
