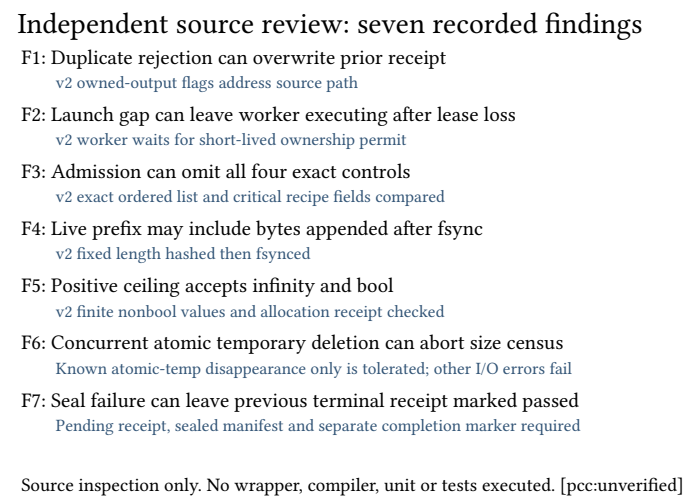
Independent durable validation source review

2026-11-05 · T-1606 · [pcc:unverified]

Read-only inspection of the proposed root-library validation wrappers. The reviewer did not author the producer wrappers and was not blind to their purpose or earlier failure. No wrapper was imported, syntax-checked, executed or tested; no compiler, unit or scientific run was started. This review records source findings and their dispositions, not runtime acceptance.



Retained controls and bindings

The candidate test, candidate pencil source and fixed fixture match the historical packet byte hashes. The actual Some/None solver control retains scalar 31124, seed 17823097723983109480, p739 and coefficient cap 25 million. The three earlier exact controls and the unfiltered default-feature library suite remain in the proposed worker. Compilation alone, zero tests or filtered-only execution cannot satisfy that suite.

V2 compares the four ordered exact test names and critical limits to the pinned recipe, requires finite nonboolean cost values, and binds publication and allocation receipt hashes. Admission remains absent. Materialized inputs, runtime qualification, current funding, resource enforcement and prospective execution release remain outstanding.

Evidence and scope

review.json binds the inspected source versions and records final source-only dispositions. findings-initial.json and the version snapshots preserve the original five defects and two follow-up findings. source-snapshots.json identifies snapshots; findings.csv and render.py provide editable graph inputs. These checks do not establish crash durability, signal behavior, filesystem behavior or successful test execution; those need a separately admitted controlled validation.

No canonical research claim, measured cost ratio, full cohort verdict or frozen historical artifact was changed. Parent coordination retains execution and publication authority.
