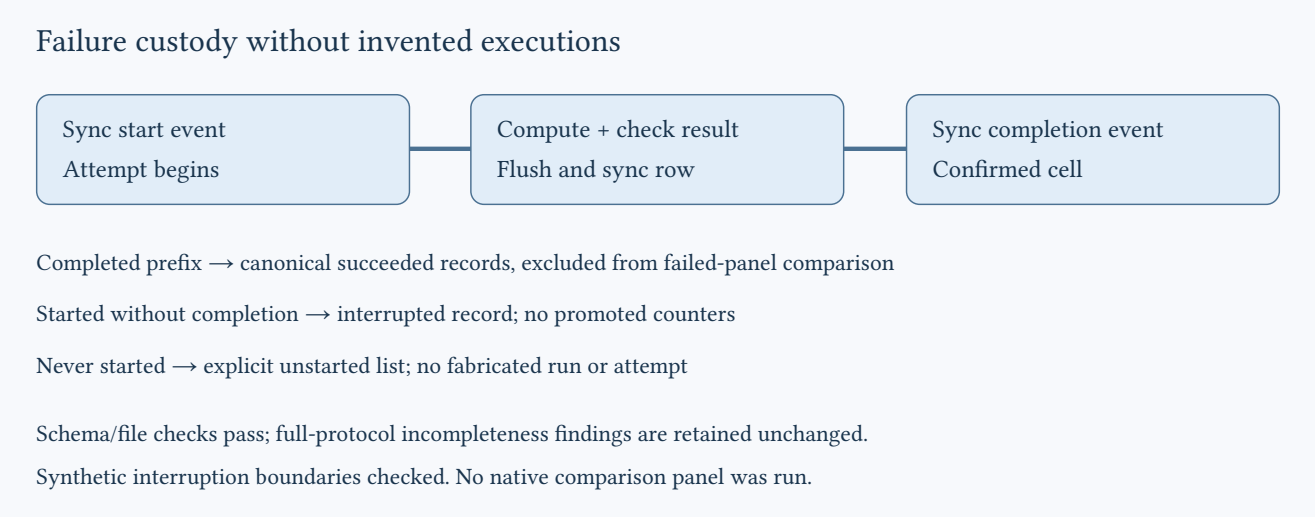
## Resultant failure-flow integration

A durable native cell-start/completion journal and two export paths now preserve partial attempts without manufacturing executions for cells that never started. All journal I/O is outside the arithmetic accounting interval.



### Checks and interpretation

Source-bound validation-01 passes native software checks, exact reverse-generation audit, canonical draft validation and four synthetic methods. Synthetic checks cover all481 journal-prefix boundaries, unconfirmed complete rows, bad sequence/pins/types/values, tails, empty and partial canonical exports, nonzero exit after full completion, and incomplete success-journal rejection. No48-case native comparison panel was executed.

Failure exports pass schema/internal/file checks and retain full-protocol completeness findings. All their run records are excluded from comparison. Successful export requires all240 completion markers and the prior value/control checks. Missing completion is not proof that arithmetic never finished.

### Next

Bind the published journal-runner source and production binary, obtain admitted build/preflight and actual remaining budget/capacity evidence, then freeze/publish. Real draft remains unadmitted; no funds reserved or cloud jobs submitted. Original4563-case cohort unchanged.

### Sources and status

Prior panel, capture/export source and pinned canonical authority at41bfaed260093c69da299cbad936205530909b6f. Producer software checks only; no independent review. Two inherited compiler warnings retained. No canonical schema change or completeness-gate bypass.
