Independent control-correction source review

Source fidelity review

5 November 2026

Disposition: scoped source fidelity supported. Exact correction `7863b3ea2c5b`; candidate `448d5ab601e9`. Machine status remains not verified. No compiler or replay occurred.

Preservation. All twenty theorem statements are unchanged. Fixture coefficients, hypotheses and controls remain intact. Manifest and published Git bytes match. No sorry, admit or axiom is added; the separate thirty-name readback and negative control are unchanged.

Corrections. Qualified residual selects the intended polynomial definition. Polynomial.C_ofNat normalizes constant-polynomial numerals before ring without changing coefficients. Indentation keeps selected-order arguments inside the same exact application. AddValuation.map_mul expands valuation of a product to the sum of valuations, matching the stated additive order identity rather than a multiplicative homomorphism.

Primary bindings. Mathlib Polynomial/Basic line451 and Valuation/Basic line1160 were inspected. Their file hashes match the prior native custody dictionary. These APIs support the intended corrections; no novel mathematical premise is introduced.

Remaining check. Source inspection does not establish complete elaboration; additional errors may remain. Three of three attempts are already used. A distinct prospectively approved execution amendment is required for any new run, retaining all four calls, thirty names, negative control and full custody. This review grants no execution or renewed clock.
