Literal mixed UInt64 dispatcher composition

Three compiled theorems combine the reviewed word branches in source decision order. Under original valid inputs, canonical coordinates and coefficients, prime $5 \le p < 2^{31}$, and four nonzero weights, the dispatcher returns Some of a canonical, valid payload with nonzero output weights.

The direct raw guards preserve cancellation precedence, mismatch failure, repeated support and the doubled-plus-generic fallback. Both generic None paths and explicit mismatch are excluded under the original premises. A separate corollary validates any returned payload.

The proof uses reviewed word components, without importing the newly composed field dispatcher awaiting review. No output-validity or positive-ordinate premise was added. Source scope explicitly requires Field.n=1 and tables=None. Pure value helpers may evaluate unused fields; side effects and counters are outside this theorem.

Final main, ten fixed p=7 controls and three-theorem axiom readback pass. Controls invoke the aggregate theorem for all four successful branches, check their tags, zero-y cancellation and invalid-input mismatch. Earlier simplification and control-instance failures are retained.

Independent review pending. No repository edits, scientific runs or cloud actions. Compiler refinement, divisor-class addition and whole-walker behavior remain separate; cost ratios are null.

Mixed 1+2: source-order UInt64 dispatcher

1. $K \neq 0$	Generic Some / common
2. $K = 0$; cancellation	Extracted point / cancellation
3. Cancellation false; mismatch	None — excluded by valid inputs
4. Positive; repeated support	Tripling Some / tripling
5. Positive; distinct support	Double + generic Some / positiveDistinct

Canonical valid inputs + nonzero weights ⟶ canonical valid Some; 10 fixed checks
