Signed producer build containment: source review

Fresh private workspace owner marker; no existing source/cache or automatic retry accepted.

All mutable cache files copied independently, exact source overlays and private membership verified; donor vendor/toolchain read-only in service.

2400 seconds total; staging and compile share 1800; worker and same-invocation supervisor only shorten deadline to 600 seconds after build.

Root-library Cargo JSON selects one test executable from exact private source target; executable hash checked before each exact test and afterwards.

Signed acceptance requires exact28 panel rows plus final completed28 after faults and positive identity/duplicate counts. Labels acceptance requires exact7 named rows.

Source hash in trace environment now binds full patched expected-source-manifest; canonical revision is explicitly base provenance.

Admission remains false with fresh post-v4 cache, ledger, lease, review, publication and serial terminal receipts pending.

Success-path post-input custody is distinct from failure paths that do not reach that check.

Two source-review findings were raised. The worker now supplies the exact patched source-manifest digest to trace identity instead of its base-file digest. The corrected post-custody prose states that failures before the final check retain unknown status.

The proposed native envelope is 2 CPUs, 16 GiB, no swap, one attempt and one active payload. Staging and build share 1,800 seconds; exact tests, checks and cleanup share at most 600 more. Bounds are stopping thresholds, not predictions of runtime fit.

The fixed test source was reviewed previously; this review inspects actual staging, binary selection, final completion checks and ownership adaptation. No compiler, test payload, cache copy or native unit was run by this review. New driver controls and the newly proposed lock-generation gate are separate source packets.

Sources checked: exact retained root-v4 machinery, signed producer source/review and immutable donor manifest c5178d21. KB tools unavailable; repository primary sources were used. Final publication and live admission are parent-owned steps.

Prospective signed qualification: checked source boundaries

Exact immutable donor → independent private copy → pinned overlays

1,800 s staging/build → selected root test binary → ≤ 600 s tests/cleanup

28 signed cases + final fault summary | 7 fixed Labels cases

Source review only; admission, runtime results and driver panel remain separate

Source-only diagram; no candidate runtime measurements.
