Additional materializer admission — inert proposal

The reviewed mapping correction and unchanged safety helper are copied byte-for-byte, with their hashes in bindings.json. preparation.json and launch.json specify new unique proposed paths and an exact prospective command. Both carry approval_required=true and launch_disabled=true. The configuration additionally has reviewed=false, published_github_commit=null and lease=null: the unchanged worker rejects it before creating output. The descriptive launch flags are operator gates, not fields enforced by the legacy worker. No launcher is provided or invoked here.

Before any release

Obtain explicit authorization for one additional attempt; the old 1/1 allowance is consumed. Create a successor admission binding that authorization, current budget, a live runtime reservation and fence, new source/config/command publication and prospective independent review. Do not silently toggle this frozen packet or reuse the source-preparation lease. Reconfirm absence of all proposed directories and unit at actual release. If any exists, refuse; a changed path requires a new published binding. Prior failure evidence remains unchanged.

CPU remains 2, physical memory 4 GiB, swap zero, tasks512, one active payload. Proposed total charge is900seconds including supervision, cleanup and sealing; native880, systemd885+5stop, timeout895+5kill remain unchanged. 46800 total minus4500 charged leaves42300; an approved900 charge would leave41400, then1800 validation leaves39600. Deadline remains2026-11-06 04:00UTC. This is arithmetic, not allocation or permission.

Effective limits and ownership readbacks

Before release record `systemctl show --property=DefaultLimitAS --property=DefaultLimitASSoft --property=DefaultLimitDATA --property=DefaultLimitDATASoft`; these manager defaults are observations, not the actual worker limits. The exact command introduces no new LimitAS/LimitDATA override. Immediately after launch capture the live InvocationID, MainPID, ControlGroup, boot ID, actual `/proc/<captured MainPID>/limits`, unit LimitAS/LimitASSoft/LimitDATA/LimitDATASoft, and cpu.max/memory.max/memory.swap.max/pids.max plus cgroup.procs/events. Capture limits only for the matched invocation/PID. Removing setrlimit does not remove inherited limits. If the worker ends before live limits can be read, preserve the missing readback and continuing mapping risk; never invent unlimited effective limits. This manual observation is not an enforced pre-Git handshake. No native success can be inferred from command exit0 alone.

Use the already reviewed OPERATE.md ownership procedure: capture identity, stop only that invocation when appropriate, verify captured group empty/absent, bind native receipt and durable output hashes. A different or unknown owner blocks further work. No automatic retry or compiler. Record actual filesystem via existing findmnt; do not copy old XFS assumptions. Preserve partial files and all errors on failure.

Materialization and validation boundary

All historical input hashes remain pinned, including revision29861c9a55f9ae5a33e1e09b3866aa397fbde605 and candidate-pencil555a5c62339a927579599d46c7e94265e52497dc56bacf0b13bb53c2dcd133c4. Complete archive/tool/cache hashing is future worker work. No materialized-inputs.json is fabricated. Only successful preparation can produce and seal that manifest; validation must then publish it with its own exact concrete admission. Existing validation scope stays default-feature offline locked root-library compile, four ordered exact controls including actual Some/None, and full unfiltered suite under1800seconds/2CPU/16GiB. The source-selection difference between materializer and validation must remain explicit.

Owner-waiver helper source inspection

owner-waiver-delta.patch compares the independently reviewed durable-v2 helper to the existing owner-waiver-v3 helper. The delta changes schema, replaces finite dollar allocation checks with hash-bound owner instruction/scope/approved fields, and adds exact deadline plus integer remaining-worker checks (at most46500). Test-list equality, attempt1/no automatic retry, recipe hashes, publication receipt, input digest, lease fields, paths, durable output handling, sealing and cleanup code are unchanged. Current42300 fits the historical ceiling; this ceiling is not a live budget ledger. This producer inspection is not an independent review, and neither helper was imported or executed. The separate independent-review gap is the waiver delta plus its future concrete admission; do not infer it passed from the v2 or mapping reviews. Owner-waiver approval must not be used as additional-attempt approval.

Sources and status

Sources checked: frozen mapping review, failed attempt cleanup/receipt, prior OPERATE.md, durable-v2 recipe/worker/review and owner-waiver source. Prior primary getrlimit and Git configuration documentation explain the virtual-address versus physical-memory distinction; exact failed mapping length remains unknown. KB tools/wrapper remain

unavailable in this sparse runtime; frozen bound source is the fallback. No new literature or performance claim. Source-only, PCC unverified; no compile, test, native execution, runtime resource or retry was started.

Additional materialization: prospective gates, no new attempt authorized

42300 seconds remaining now; proposed charges and future results are not observations.
