Finite-field pruning preserves all sets and saves no through-rank systems

All 21 saved-tape cases pass the counterfactual finite-Fp rejection audit. The 77-test software gate, proof and integer replay are recorded separately. No polynomial collector or BSGS oracle was repeated by this audit.

Complete observed counts

Each arm tests 1,957,992 finite signed peels over the same 9,658 residuals. The full-stream rejection counts are phi 1, doubling 2, pure 0. All rejected presentations were already unsuccessful in the saved oracle. There are zero false rejections on all 21 cases in each arm.

Arm	Tuples retained	Projective rows retained	Full-rank cases	Rejections through first full rank
Phi	1,865	1,698	21/21	0
Doubling	1,804	1,705	21/21	0
Pure	441	417	21/21	0

Every saved physical presentation, unique physical tuple and projective row is preserved. Independent RREF gives the original rank, the identical first full-rank query and verified target/factor points in every case. All finite systems through rank remain: phi 275,784, doubling 260,496, pure 1,062,000. These are sums of separate case counters, not pooled ranks or amortized DLP prices. Infinity is retained by the rule; the actual-point exception test is in the software report.

Interpretation and evidence

This predicate supplies no system-count saving before recovery on this tape. Its proof and successful preservation audit do not establish a useful collector improvement. No filter is deployed and no new elapsed time or complete price is admitted. A different workload could differ; this is not an impossibility claim for other pruning or joint algorithms.

Native source and frozen runner are the same as the software gate (../run-20261024T0607Z-pruning-software/REPORT.md). The full native summary is runs/fp-pruning-audit-v1/summary.json, SHA-256 e8122030c1d0255630a3a50425c3fe37f1daf75f5491be368a2621bda49e8903. results/fp-pruning-v1-headline.json is a direct field projection of that summary; it performs no new aggregation. Per-case records, input/reference hashes, actual commands and exits remain in the raw run. One Rust worker, 8 GiB, 1,200 seconds per case and the shared busy reservation apply. No benchmark-index or leaderboard row is promoted.
