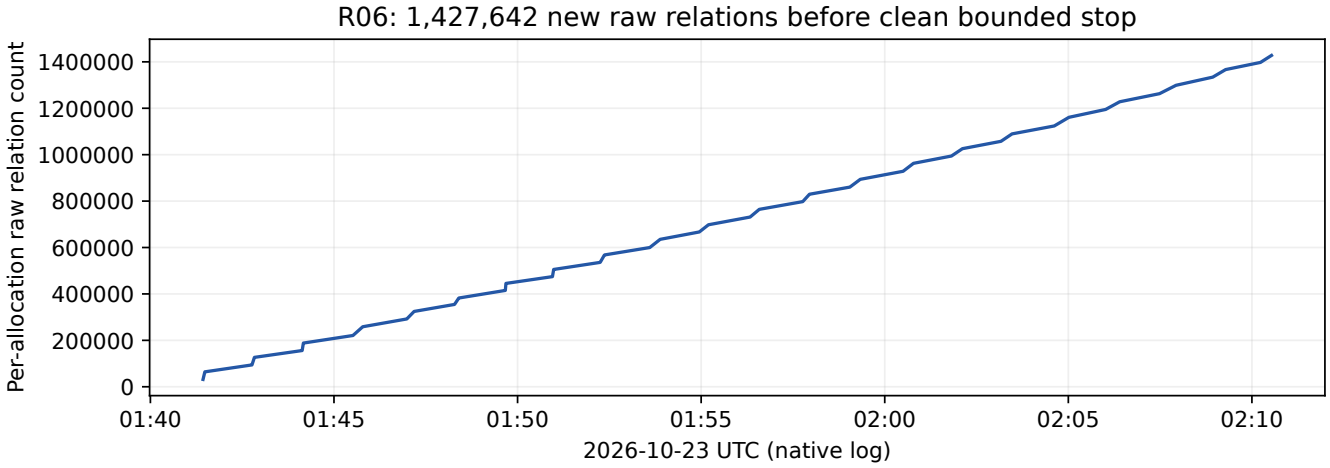
R06 completion: corrected stop, unchanged factorization

R06 stopped at 2026-10-23 02:10:32 UTC with native exit 0 after its configured 1800-second allocation. Both workers printed the corrected timeout value; native elapsed output was 1827.6341 seconds as outstanding work ended. No outer timeout signal was logged. No proper factor was returned. This is a clean bounded execution, not completed factorization.



The graph shows native counters and UTC log timestamps for one allocation, with no replicate interval, throughput comparison or completion estimate. Its data exclude inherited relations. The final counter is 1,427,642 new raw relations; the final main-file count is 4,592,399, including 3,164,757 inherited lines. These are raw counts, not a rank claim.

Input, execution and verification

The exact target is skipped_256_876-twist2, the imported P-256 block-876 512-bit degree-2 extension-twist order. Its still-composite residual has 444 bits. The certified partition remains 1657 times 45294121 times 5333949541 times that same residual. The protocol binds the literal and predecessor archive checksum. Runtime source was copied and blob-checked against b08dc783f5ba6c3ef821218ff772fe16cc28cee1.

Patched YAFU and unchanged native lattice sievers used two threads, seed 20261022, -gnfs -xover 81 -pbatch 120, native 1800 seconds, outer 1860 seconds plus 30-second kill grace, 4 GiB virtual memory per process and 1 GiB per output file. Host allocation was four CPUs and 16 GiB RAM, L0 shared host. The actual native command and source/executable hashes are in the full raw archive. The original dated interim report and observation remain unchanged.

The separate inherited 32,684-line worker output was quarantined without editing; native range selection recomputed the missing gap. Post-run refinement and a separate prime/product replay both pass. All three proven prime certificates are retained. Fresh native checks verify the exact input and common root in both selected polynomial formats; the saved master still has 329 validated records. Existing Lean partition products remain applicable; primality is established separately by PARI certificates. No new algebraic identity or stronger factorization claim is introduced.

The archive manifest and validation identify the complete raw bytes, fresh restoration, checksum checks and canonical repack. Source snapshots, commands, prior history, state, generated certificates, stdout/stderr and the quarantined worker are preserved. Bulk publication still needs the required artifact-store setup; no remote upload is claimed.

Subsequent check and remaining requirement

The retained October 25 FactorDB GET response returns C and the exact residual as its only factor. It supplies no new divisor. Its original headers and timestamps are retained beside the response. This is a dated database observation, not a priority claim.

R07 separately filters an independent copy of these relations. Native duplicate removal retains 4,518,304 unique relations including generated free relations; singleton removal leaves 92, and no matrix is generated. That diagnostic preserves the original R06 source and is reported separately.

Eight of nine timeout integers and thirteen of fourteen fields remain resolved. A complete prime-certified split of the remaining 444-bit cofactor is still required. The merged PR #2379 delivered the earlier evidence and timeout correction; this completion record is its follow-up. A clean stop and more raw relations establish neither a security result nor a historical skip explanation. Existing mathematical and IC performance graphs have no changed conclusion and remain unchanged; this new operational graph records the completed allocation.
