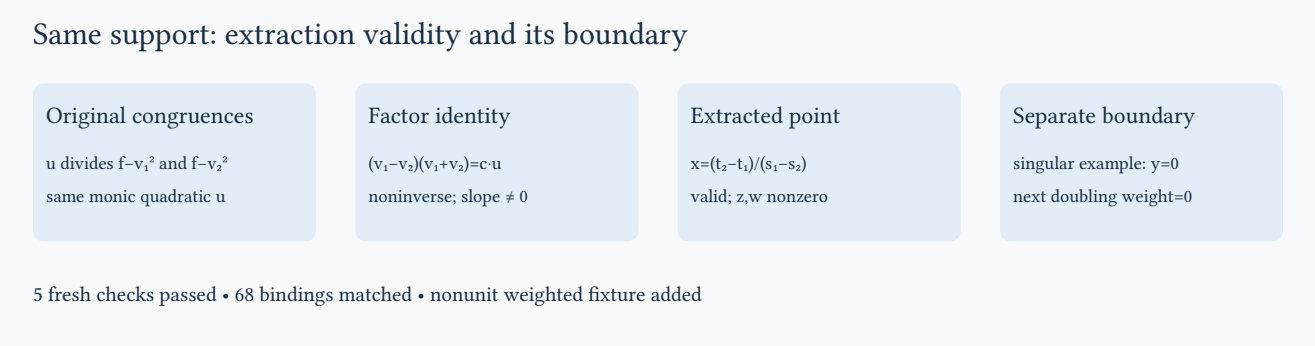
Independent same-support extracted-point review

Result: validated at the field extraction scope. Seven declarations derive point validity and nonzero representation weights from original congruences and explicit normalized branch premises. No output-validity or smoothness assumption is hidden.

The factor identity $(v_1-v_2)(v_1+v_2)=c\cdot u$ follows by a degree bound. The noninverse premise and nonzero slope difference justify the extracted support root. Literal source cross-weights and normalized coordinates match the retained add22 extraction.

The singular fixture $f=X^5, u=X^2, v_1=X, v_2=2X$ yields a valid extracted point with $y=0$. The following doubling weight is also zero. Thus this theorem does not establish the next doubling's nonzero weight. The inverse-pair negative control remains explicit.

A reviewer nonunit-weight fixture on $f=X^5-X+1$ applies the source theorem and independently simplifies the extracted point to (1,1). All five fresh checks passed, and all 68 manifest/source bindings matched. Seven axiom readbacks contain only standard Lean axioms.


Reviewer dependency involvement is disclosed. Existing pinned binaries were reused. Raw-word guard composition, smoothness-to-nonzero ordinate, subsequent doubling, class addition and compiler/counters remain separate. No scientific runs or producer edits occurred; cost ratios are null.
