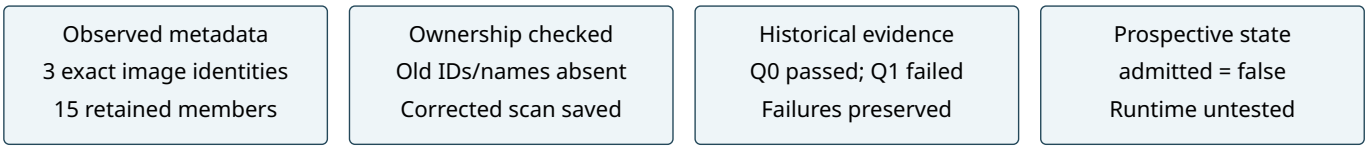
Runtime binding reconciliation archive

Archived observations from 2026-11-01 at 20:12-20:13 UTC bind the existing base and runtime image identities and the proposed context sources. This packet preserves that completed read-only inspection; packaging performed no Docker, cloud, scientific or proof execution. The binding ledger explicitly records admitted=false.



Observed metadata. Three exact images were present as linux/amd64 with empty OnBuild: upstream, approved existing base and historical runtime. Base and runtime owner labels, retained tags and layer lists are recorded in evidence/binding-ledger.json and the raw observations. Image IDs are preserved in full there. The 15 retained runtime members matched their recorded type, mode and SHA256; two proposed empty 0644 mountpoint files matched the published proposal. This maps proposed context paths to observed source bytes; context_staged remains false.

Ownership reconciliation. Both retained Q0/Q1 container IDs and both exact names were absent. No cleanup was performed. The corrected process scan found no exact retained assembly, recovery or qualification script path or owned build-tag argument. The first scan used two incorrect script names and remains preserved beside the correction. These timestamped observations are not continuous monitoring or a claim about unrelated jobs.

Preserved failures. The original assembly receipt remains uncertain after an IID-file permission error, with its terminal build-client exit recorded separately. The later exact-base adoption/runtime completion receipt remains distinct. Historical qualification passed Q0 and failed Q1 on writable-layer differences; its cleanup receipt remains complete. These are historical results, not new qualification attempts.

Unresolved bindings. Image inspection does not expose filesystem ancestor types or modes. Relevant parent paths and future placeholder metadata remain unknown; no container creation, export or save was used. No corrected image exists in this record: new_image_id and qualification_receipt are null. Empty writable-layer diff remains an untested hypothesis. Next inputs are a staged-context inventory, admitted parent-path inspection, amended assembler bindings and independent review, and explicit execution limits/admission. Existing budgets and the expired scientific deadline are unchanged.

Sources and scope. This archive uses evidence/REPORT.md, binding-ledger.json, proposed-context-member-ledger.json, commands.json, observations and historical receipts; related published packets are runtime-mountpoint-proposal and runtime-mountpoint-review. Their existing Dockerfile reference review supplies the method basis; no new method or literature claim is introduced. The diagram shows evidence and admission state because there are no comparable research measurements. Canonical scientific graphs are unchanged. Reproduction checks bytes and renders only; archived scripts containing Docker commands must not be run automatically.
