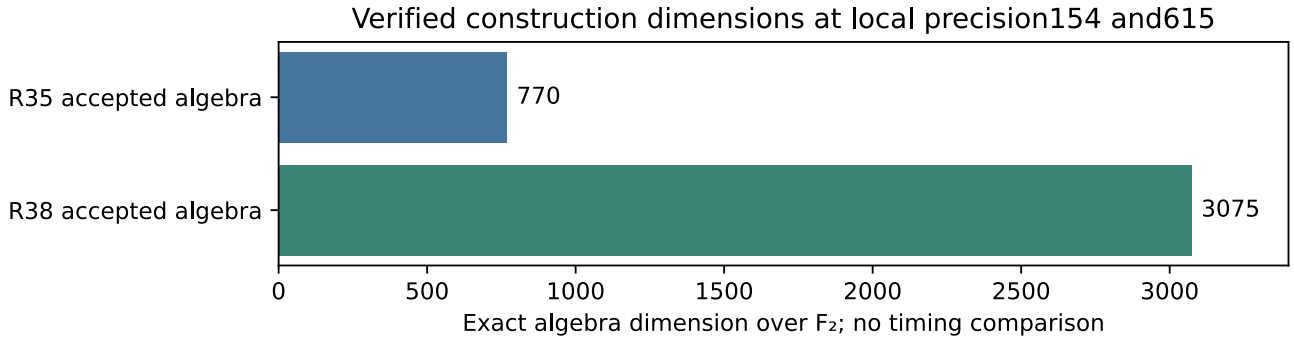
Koblitz transfers — R38

Larger exact evaluation algebra; no IC performance claim

At the certified degree-five point Q, construct F2[t]/$(t^5+t^3+1)^{615}$, dimension 3075. Every one of the3075 inverse columns and all pivots are recombined.

The actual coefficient-field embedding, ring identities and corrupt inverse/ field controls pass under the unchanged native4GiBvirtual/1200s caps.



A pinned Lean lemma proves coefficient extraction at precision615 under explicit characteristic-two, residue-period32 and nilpotence hypotheses. It compiles and passes the transitive axiom audit with zero failing and zero trusted declarations. Native arrays and proper geometry are not formalized.

For the proposed baseD1=4D0 of degree512, evaluation at615Q has degree3075, exceeding the L(6D1) pole bound3072 under the retained proper/pole bridge. This can support the next larger construction, but615 source jets and the complete section spaces of prospective dimensions452,1476,3012 are not built.

The degree367 gap can use29Q. The degree460 gap52 needs additional certified support or a local line-bundle trivialization; degree-five copies alone do not fill it. Actual larger support evaluation and factor images remain open.

No larger-n Koblitz transfer, IC relation rank, speed comparison, scalar recovery or independent external replay is claimed. Lean4.34.1/mathlibd13f23b, -j1-M4096/1200s. Global metric integration awaits exclusive scope release. See R37/METRICS_PENDING.md, NEXT.md and retained exact inputs/certificates.
